

# TEK4090 – Introduction to Modern Control

## Assignment 4 v1.0

### Part 1 of 3

Due: December 5 2025, 23:30

---

1. (30 points) In this task, you will develop a mildly under-developed model-predictive control routine. The routine I am giving you has a bug, and you will have to figure out what I did wrong. Then, you will have to implement new modality into the code. The hard parts of this question are in (f), so make sure you give yourself enough time to do them.

- (a) For a prediction horizon of  $k = 0, \dots, T - 1$ , write the constraints

$$z_0 = \bar{z} \tag{1}$$

$$z_{k+1} = Az_k + Bu_k, \quad k = 0, \dots, T - 1 \tag{2}$$

in the form

$$\Psi x - \Omega z_0 = 0 \tag{3}$$

where

$$x = [z_1^T \quad \dots \quad z_T^T \quad u_0^T \quad \dots \quad u_{T-1}^T]^T := \begin{bmatrix} z \\ u \end{bmatrix} \tag{4}$$

- (b) What cost function does the code encode?
- (c) What system is the code trying to simulate, and does it have a name? What are the lower and upper bounds on the state and input constraints?
- (d) Run the code. Note that it terminates due to an error at approximately  $kk = 14$ . Debug the error, and describe what was happening. Plot the response of the system. Hint: look at the optimal control inputs and resulting states after propagating.
- (e) How would you change the cost function in part (b) to encode a penalty on the output  $y_k = Cz_k$ , instead of the state  $z_k$ ? Would you change the constraint in part (a) as well?
- (f) Notice that there is a  $y^d$ , or ‘desired trajectory’ variable that is unused in line 29 or thereabouts. By using a quadratic penalty on  $(y_l - y_k^d)$ , re-write the debugged code so that the system tries to track this trajectory. You may find the following hints helpful:
- The desired trajectory is outside the system boundary. When you are close to the system boundary, process noise may push the system beyond the boundary, rendering the optimization problem infeasible and thus the

code stops. This is bad. In order to fix this, you can use a ‘slack variable’  $\sigma$  on the state  $z_k$  dynamics constraint:

$$\begin{bmatrix} -5 \\ -\infty \end{bmatrix} \leq z_k \leq \begin{bmatrix} 5 \\ \infty \end{bmatrix} \rightarrow \begin{bmatrix} -5 - \sigma_k^l \\ -\infty \end{bmatrix} \leq z_k \leq \begin{bmatrix} 5 + \sigma_k^u \\ \infty \end{bmatrix} \quad (5)$$

The point of  $\sigma_i^{l,u}$  is that it is always zero, except when  $z_k$  is close to the boundary. Then, if  $z_k$  goes over the boundary, instead of the problem becoming infeasible, the system accrues some slack variable penalty. Therefore, you should also introduce an appropriate quadratic penalty on  $\sigma$ .

- To implement the slack variable, you will need to use the  $A_{\text{ineq}}$  and  $b_{\text{ineq}}$  entries of `quadprog`, and append the slack variable somehow to all the matrices that are entering `quadprog`:

$$\begin{bmatrix} z \\ u \end{bmatrix} \rightarrow \begin{bmatrix} z \\ u \\ \sigma^u \\ \sigma^l \end{bmatrix} \quad (6)$$

- Right now, the linear part of the cost  $f$  is zero. When you implement the desired trajectory by penalizing  $(y_k - y_d^k)$ , you will get a linear term when you expand the quadratic. This is what forms  $f$ . The constant term can be discarded, since a constant term isn’t affected by the variable, and so discarding it doesn’t change the optimizer.

**Ans:**

(a) We know that the equation

$$\begin{bmatrix} z_1 - Az_0 - Bu_0 \\ z_2 - Az_1 - Bu_1 \\ \vdots \\ z_T - Az_{T-1} - Bu_{T-1} \end{bmatrix} = 0$$

must be satisfied. We also have that.  $x = \begin{bmatrix} z \\ u \end{bmatrix} = \begin{bmatrix} z_1 \\ \vdots \\ z_T \\ u_0 \\ \vdots \\ u_{T-1} \end{bmatrix}$  where  $z_k \in \mathbb{R}^n$ ,

$u_k \in \mathbb{R}^m$  and thus,  $u \in \mathbb{R}^{nT}$ ,  $u \in \mathbb{R}^{mT}$ . We know furthermore that each row block enforces the eq

$$z_{k+1} = Az_k + Bu_k$$

The block matrix structure then becomes

$$\Psi = \begin{bmatrix} I_n & 0 & \cdots & 0 & -B & 0 & \cdots & 0 \\ -A & I_n & \cdots & 0 & 0 & -B & \cdots & 0 \\ 0 & -A & \ddots & 0 & 0 & 0 & \ddots & 0 \\ \vdots & \vdots & \ddots & I_n & \vdots & \vdots & \ddots & -B \\ 0 & 0 & \cdots & -A & I_n & 0 & \cdots & 0 \end{bmatrix} \in \mathbb{R}^{nT \times (nT+mT)}$$

and

$$\Omega = \begin{bmatrix} A \\ 0 \\ \vdots \\ 0 \end{bmatrix} \in \mathbb{R}^{nT \times n}$$

If we for verification place  $K=3$  we get that the equation

$$\Psi x - \Omega z_0 = 0$$

indeed becomes true

$$\begin{aligned} \begin{bmatrix} 1 & 0 & -B & 0 \\ -A & 1 & 0 & -B \end{bmatrix} \begin{bmatrix} z_1 \\ z_2 \\ u_0 \\ u_1 \end{bmatrix} - \begin{bmatrix} A \\ 0 \end{bmatrix} z_0 &= \begin{bmatrix} z_1 - Bu_0 - Az_0 \\ -Az_1 + z_2 - Bu_1 \end{bmatrix} = 0 \\ \rightarrow \begin{bmatrix} z_1 \\ z_2 \end{bmatrix} &= \begin{bmatrix} Az_0 + Bu_0 \\ Az_1 + Bu_1 \end{bmatrix} \end{aligned}$$

(b) The cost function that the code is encoding is

$$J = \sum_{k=1}^T z_k^T Q z_k + \sum_{k=0}^{T-1} u_k^T R u_k$$

(c) The system that the code is trying to simulate is the discrete time LTI double integrator system with a gaussian process and measurement noise. The states are position and velocity, while the inputs are acceleration. The output is the position

$$A = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, B = \begin{bmatrix} 0.5 \\ 1 \end{bmatrix}, C = \begin{bmatrix} 1 & 0 \end{bmatrix}$$

The bounds are

- $-f \leq z_1 \leq 5$

- $-\infty < z_2 < \infty$
- $-1 \leq u \leq 1$

(d) I have made a figure that plots the velocity, position and the input  $u$  right before the error in the code occurred.

The code fails because the MPC QP problem becomes infeasible. What's happening here is that the position  $z_1$  is pushed outside of its domain  $[-5, 5]$ . Given the input constraints and disturbances, there is no control sequence that can keep the position inside the bounds  $[-5, 5]$ . This is why the code stops after circa 14 iterations, because the QP has no feasible solution and the quadprog returns an error which causes the loop to stop. The control signal shows that it's reached its limit before the loop stops, which explains why the controller can't keep the position within its bounds.

(e) To penalize the output, we replace the cost function

$$J = \sum_{k=1}^T z_k^T Q z_k + \sum_{k=0}^{T-1} u_k^T R u_k$$

with  $y_k = C z_k$

$$\begin{aligned} J &= \sum_{k=1}^T (C z_k)^T Q (C z_k) + \sum_{k=0}^{T-1} u_k^T R u_k \\ &= \sum_{k=1}^T z_k^T (C^T Q C) z_k + \sum_{k=0}^{T-1} u_k^T R u_k \end{aligned}$$

The constraints will remain the same. The MPC used to track the states, and now we track the output instead

(f) Here is a plot of the implemented code

This does a much better job at tracking the sinusoidal reference that was defined in line 29 of the code.

To avoid infeasibility when the reference pushed  $z_{1,k}$  near the boundaries  $[-5, 5]$ , the slack variables  $\sigma_k^u, \sigma_k^l \geq 0$  were introduced for each step  $k = 1, \dots, T$ , which modifies the state constraints to

$$-5 - \sigma_k^l \leq z_{1,k} \leq 5 + \sigma_k^u$$

These slack variables are appended to the decision vector

$$x = \begin{bmatrix} z \\ u \\ \sigma^u \\ \sigma^l \end{bmatrix}$$

In the code, this required extending  $A_{ineq}, b_{ineq}$  to implement  $z_{1,k} - \sigma_k^u \leq 5, -z_{1,k} - \sigma_k^l \leq 5$ . A large quadratic penalty was added to  $\sigma_k^u, \sigma_k^l$  in the cost to keep violations small.

When we introduced the reference tracking  $y_k - y^d = Cz_k - y_d$  we got that the expression  $(Cz_k - y_k^d)^T Q_y (Cz_k - y_k^d)$  expanded to a quadratic, a linear and a constant term. We dropped the constant term from the function because it's irrelevant to optimization, and got

$$J = \sum_{k=1}^T z_k^T C^T Q_y C z_k - 2(y_k^d)^T Q_y C z_k + \sum_{k=0}^{T-1} u_k^T R u_k$$

where  $Q_y = 1$ , this is because  $C = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$  and  $y_k = Cz_k = \begin{bmatrix} 1 \\ 0 \end{bmatrix} z_k = z_{1,k}$ .  
Therefore

$$C^T Q_y C = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}$$

. The first term acts as a quadratic penalty on  $z_{1,k}$ . The second linear term  $-2y_k^d z_{1,k}$  is important because it's what makes the MPC follow the time varying reference. If we don't include this term, the controller would simply drive the position state toward zero rather than track  $y_k^d$ .
